More information about banks and civil engineering structures can be found on our website:

Banks and civil engineering structures

The bank acts as the separation zone between water and land and makes an important contribution to biodiversity. We always integrate the design of banks and civil engineering structures into their surroundings as well as possible. The ecological value of the area is always a fixed element of our design.

Bank management plans

To tackle maintenance of bank protection in a structured way and to carry out management tasks in combination, insight into the state of maintenance is required. Our field workers assess both the technical and the functional condition of banks and revetments, check the basic characteristics and look at the opportunities for nature-friendly banks. Our advisers translate inspection data into a management plan or provide specific advice on replacing or repairing bank protection. A bank management plan gives insight into the expected costs and the prioritisation for replacing revetments.

Nature-friendly banks

We look for opportunities for the construction of nature-friendly banks, design nature-friendly banks and supervise their construction. Nature-friendly banks often require no bank structures, which saves timber, plastic and metal.

Bank structure

When designing a bank structure, we take into account the load on the structure and the soil composition. To determine this, we carry out boreholes and cone penetration tests and make use of existing data. Using all the data, the structure is calculated and designed. We work as circularly as possible: materials are reused wherever possible.

Civil engineering structures

Civil engineering structures are water management structures, such as jetties, culverts and weirs. When constructing culverts, we try to plan fauna passages. For a weir, we look for opportunities to construct a fish ladder. We think from a technical perspective, but always take into account the ecological value of the area.
